

Implementing boolean operations for generalized Büchi automata

Generalized Büchi Automata

- An acceptance condition is a **generalized Büchi condition** if there are sets $F_1, \dots, F_k \subseteq Q$ of accepting states such that a run ρ is accepting iff it visits each of F_1, \dots, F_k infinitely often.

$$F_1 = \{q\}$$

$$F_2 = \{r\}$$

From NGAs to NBAs

- Important fact:

All the sets F_1, \dots, F_k are visited infinitely often

is equivalent to

F_1 is eventually visited

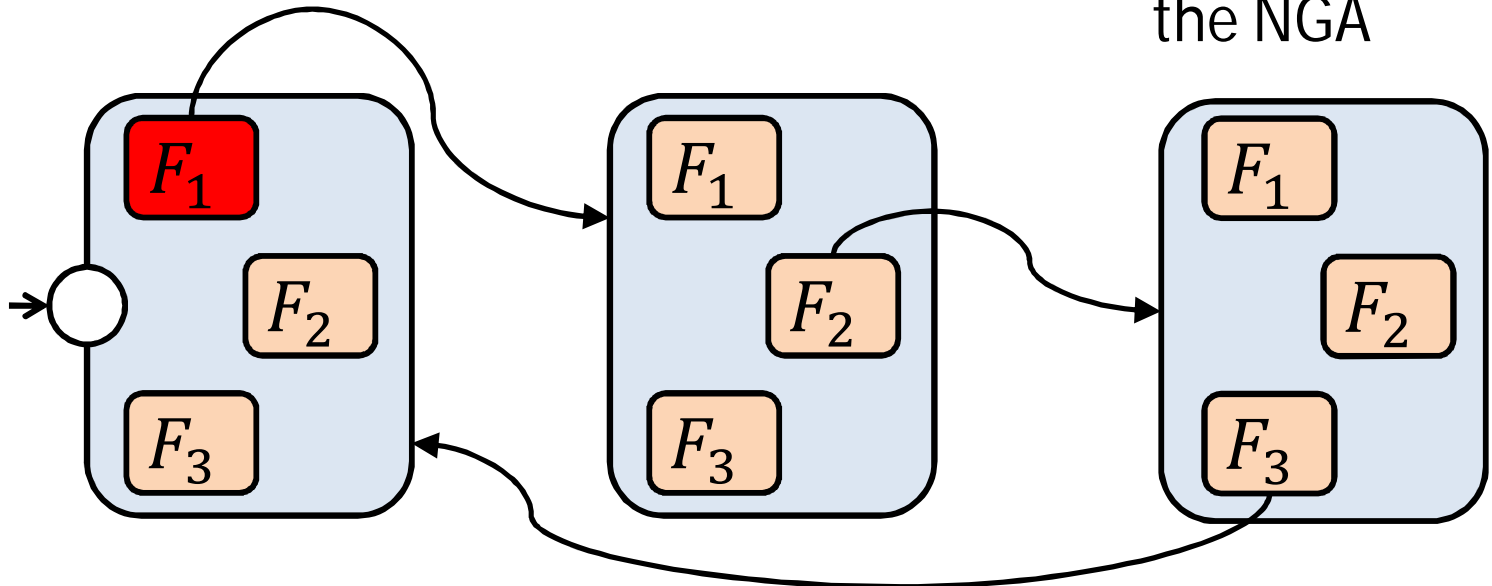

and for every $1 \leq i \leq k$

every visit to F_i is eventually followed by a visit to " $F_{i \oplus 1}$ "

From NGAs to NBAs

NFA with 3 sets
of accepting
states

Equivalent NBA
with 3 copies of
the NFA

NGAtoNBA(A)

Input: NGA $A = (Q, \Sigma, Q_0, \delta, \mathcal{F})$, where $\mathcal{F} = \{F_0, \dots, F_{m-1}\}$

Output: NBA $A' = (Q', \Sigma, \delta', Q'_0, F')$

```
1   $Q', \delta', F' \leftarrow \emptyset; Q'_0 \leftarrow \{[q_0, 0] \mid q_0 \in Q_0\}$ 
2   $W \leftarrow Q'_0$ 
3  while  $W \neq \emptyset$  do
4    pick  $[q, i]$  from  $W$ 
5    add  $[q, i]$  to  $Q'$ 
6    if  $q \in F_0$  and  $i = 0$  then add  $[q, i]$  to  $F'$ 
7    for all  $a \in \Sigma, q' \in \delta(q, a)$  do
8      if  $q \notin F_i$  then
9        if  $[q', i] \notin Q'$  then add  $[q', i]$  to  $W$ 
10       add  $([q, i], a, [q', i])$  to  $\delta'$ 
11      else  $/* q \in F_i */$ 
12        if  $[q', i \oplus 1] \notin Q'$  then add  $[q', i \oplus 1]$  to  $W$ 
13        add  $([q, i], a, [q', i \oplus 1])$  to  $\delta'$ 
14  return  $(Q', \Sigma, \delta', Q'_0, F')$ 
```

NGA

$$F_1 = \{q\}$$

$$F_2 = \{r\}$$

NBA

Union of NGA: The NBA case

- Let $A_1 = (S_1, \{F_1\})$ and $A_2 = (S_2, \{F_2\})$
- Let S be the result of putting S_1 and S_2 „side by side“
$$S := (Q_1 \cup Q_2, \Sigma, \delta_1 \cup \delta_2, Q_{01} \cup Q_{02})$$
- Which NGA recognizes $L(A_1) \cup L(A_2)$?
 - $(S, \{F_1 \cup F_2\})$
 - $(S, \{F_1, F_2\})$

Union of NGA: Another case

- Let $A_1 = (S_1, \{F_1^1, F_1^2\})$ and $A_2 = (S_2, \{F_2^1, F_2^2\})$
- Let S be the result of putting S_1 and S_2 „side by side“
$$S := (Q_1 \cup Q_2, \Sigma, \delta_1 \cup \delta_2, Q_{01} \cup Q_{02})$$
- Which NGA recognizes $L(A_1) \cup L(A_2)$?
 - $(S, \{F_1^1 \cup F_2^1 \cup F_1^2 \cup F_2^2\})$
 - $(S, \{F_1^1 \cup F_2^1, F_1^2 \cup F_2^2\})$
 - $(S, \{F_1^1 \cup F_2^1, F_1^1 \cup F_2^2, F_1^2 \cup F_2^1, F_1^2 \cup F_2^2\})$

Union of NGA: The general case

- Let $A_1 = (S_1, \{F_1^1, \dots, F_1^k\})$

$$A_2 = (S_2, \{F_2^1, \dots, F_2^k, F_2^{k+1}, \dots, F_2^{k+l}\})$$

- Let S be the result of putting S_1 and S_2 „side by side“

$$S := (Q_1 \cup Q_2, \Sigma, \delta_1 \cup \delta_2, Q_{01} \cup Q_{02})$$

- The following NGA recognizes $L(A_1) \cup L(A_2)$

$$A = \left(S, \left\{ \begin{array}{cccc} F_1^1 & F_1^k & Q_1 & Q_1 \\ \cup & \dots & \cup & \dots & \cup \\ F_2^1 & F_2^k & F_2^{k+1} & \dots & F_2^{k+l} \end{array} \right\} \right)$$

Intersection of NGA: The NBA case

- Let $A_1 = (S_1, \{F_1\})$ and $A_2 = (S_2, \{F_2\})$

- Let S be the pairing of S_1 and S_2

$$S := (Q_1 \times Q_2, \Sigma, \delta, Q_{01} \times Q_{02})$$

where $\delta([q_1, q_2], a) = \delta(q_1, a) \times \delta(q_2, a)$

- Which NGA recognizes $L(A_1) \cap L(A_2)$?
 - $(S, \{F_1 \times F_2\})$
 - $(S, \{F_1 \times Q_2, Q_1 \times F_2\})$

Intersection of NGA: The general case

- Let $A_1 = (S_1, \{F_1^1, \dots, F_1^k\})$, $A_2 = (S_2, \{F_2^1, \dots, F_2^l\})$
- Let S be the pairing of S_1 and S_2

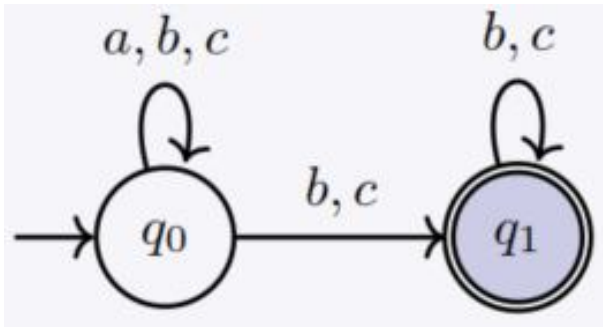

$$S := (Q_1 \times Q_2, \Sigma, \delta, Q_{01} \times Q_{02})$$

where $\delta([q_1, q_2], a) = \delta(q_1, a) \times \delta(q_2, a)$

- The following NGA recognizes $L(A_1) \cap L(A_2)$:

$$\left(S, \underbrace{\{F_1^1 \times Q_2, \dots, F_1^k \times Q_2, Q_1 \times F_2^1, \dots, Q_1 \times F_2^l\}}_{k+l} \right)$$

Intersection of NGA: The general case

Special case

- The intersection of $(S_1, \{F_1\})$ and $(S_2, \{F_2\})$ is $([S_1, S_2], \{F_1 \times Q_2, Q_1 \times F_2\})$
- Not a NBA in general.
- However, if $F_1 = Q_1$ then $\{F_1 \times Q_2, Q_1 \times F_2\}$ can be replaced by $\{Q_1 \times F_2\}$, and so the result is again a NBA.

Complementation of NGA

- Given a NBA A , we construct a NBA B such that $L_\omega(B) = \overline{L_\omega(A)}$
- We can then complement a NGA by transforming it first into a NBA
- Complementation construction radically different from the one for NFAs.

Problems

- The powerset construction does not work.

- Exchanging final and non-final states in DBAs also fails.

Solution

- Extend the idea used to determinize co-Büchi automata with a new component.
- Recall: a NBA accepts a word w iff some path of $dag(w)$ visits final states infinitely often.
- **Goal:** given NBA A , construct NBA \bar{A} such that:

A rejects w
iff
no path of $dag(w)$ visits accepting states of A i.o.
iff
some run of \bar{A} visits accepting states of \bar{A} i.o.
iff
 \bar{A} accepts w

Running example

Rankings

- Mappings that associate to every node of $dag(w)$ a **rank** (a natural number) such that
 - ranks never increase along a path, and
 - ranks of accepting nodes are even.

Odd rankings

- A ranking is **odd** if every infinite path of $dag(w)$ visits nodes of odd rank i.o.

Odd rankings

Goal: given NBA A , construct NBA \bar{A} such that:

A rejects w
iff
no path of $dag(w)$ visits accepting states of A i.o.
iff
 $dag(w)$ has an odd ranking
iff
some run of \bar{A} visits accepting states of \bar{A} i.o.
iff
 \bar{A} accepts w

Odd rankings

Prop:

no path of $dag(w)$ visits accepting states of A i.o.
iff
 $dag(w)$ has an odd ranking

Further, all ranks of the odd ranking are in the range $[0, 2n]$, and all states of the first level rank have rank $2n$.

Proof:

(\Leftarrow): In an odd ranking of $dag(w)$, ranks along infinite paths stabilize to odd values.

Therefore, since accepting nodes have even rank, no path of $dag(w)$ visits accepting nodes i.o.

Odd rankings

(\Rightarrow): Assume no path of $dag(w)$ visits accepting states of A i.o.

Define an odd ranking of $dag(w)$ as follows:

- Construct a sequence $D_0 \supseteq D_1 \supseteq D_2 \cdots \supseteq D_{2n} \supseteq D_{2n+1}$ of dags, where
 - a) $D_0 = dag(w)$
 - b) D_{2i+1} is the result of removing from D_{2i} all nodes with finitely many descendants.
 - c) D_{2i+2} is the result of removing all nodes of D_{2i+1} with no accepting descendants (a node is a descendant of itself).
- We define the rank of a node of $dag(w)$ as the index of the unique dag D_j in the sequence such that the node belongs to D_j but not to D_{j+1} .

- **Even step:** remove all nodes having only finitely many successors.
- **Odd step:** remove nodes with no accepting descendants

- This definition of rank guarantees :
 1. Ranks along a path cannot increase.
 2. Accepting states get even ranks, because they can only be removed from dags with even index.
- It remains to prove:
 - every node gets a rank, i.e., $D_{2n+1} = \emptyset$.
- A **round** consists of two steps, an **even step** from D_{2i} to D_{2i+1} , and an **odd step** from D_{2i+1} to D_{2i+2} .

- Each level of a dag has a **width**

- **Width of a dag:** largest level width that appears infinitely often.
- Since no path of $dag(w)$ visits accepting states of A i.o., each round decreases the width of the dag by at least 1.
- Since the initial width is at most n , after at most n rounds the width is 0 , and then a last step removes all nodes.

- Goal:

$dag(w)$ has an odd ranking
iff
some run of \bar{A} visits accepting states of \bar{A} i.o.

- Idea: design \bar{A} so that
 - its runs on w are the rankings of $dag(w)$, and
 - its accepting runs on w are the odd rankings of $dag(w)$.

Representing rankings

$$\begin{bmatrix} 2 \\ \perp \end{bmatrix} \xrightarrow{a} \begin{bmatrix} 1 \\ 2 \end{bmatrix} \xrightarrow{b} \begin{bmatrix} 1 \\ \perp \end{bmatrix} \xrightarrow{a} \begin{bmatrix} 1 \\ 0 \end{bmatrix} \xrightarrow{a} \begin{bmatrix} 1 \\ 0 \end{bmatrix} \dots$$

Representing rankings

Representing rankings

$$\begin{bmatrix} 1 \\ \perp \end{bmatrix} \xrightarrow{a} \begin{bmatrix} 1 \\ 0 \end{bmatrix} \xrightarrow{b} \begin{bmatrix} 0 \\ \perp \end{bmatrix} \xrightarrow{a} \begin{bmatrix} 0 \\ 0 \end{bmatrix} \xrightarrow{b} \begin{bmatrix} 0 \\ \perp \end{bmatrix} \dots$$

We can determine if $\begin{bmatrix} n_1 \\ n_2 \end{bmatrix} \xrightarrow{l} \begin{bmatrix} n'_1 \\ n'_2 \end{bmatrix}$ may appear in a ranking by just looking at n_1, n_2, n'_1, n'_2 and l : ranks should not increase.

First draft for \bar{A}

- \bar{A} for or a two-state A (more states analogous):
 - **States**: all $\begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$ where $0 \leq x_i \leq 2n = 4$ or $x_i = \perp$ and accepting states of A get even rank or \perp .
 - **Initial state**: all states of the form $\begin{bmatrix} n_1 \\ \perp \end{bmatrix}$
 - **Transitions**: all $\begin{bmatrix} n_1 \\ n_2 \end{bmatrix} \xrightarrow{a} \begin{bmatrix} n'_1 \\ n'_2 \end{bmatrix}$ s.t . ranks do not increase
- The runs of the automaton on a word w correspond to all the rankings of $dag(w)$.
- Observe: \bar{A} is a NBA even if A is a DBA, because there are many rankings for the same word.

Accepting states?

- The accepting states should be chosen so that a run is accepted iff its corresponding ranking is odd.
- Problem: no way to do so when the only information of a state is the ranking.

Owing states and breakpoints

- We use **owing states** and **breakpoints** again:
 - A **breakpoint** of a ranking is now a level of the ranking such that no node of the level owes a visit to a node of odd rank.
 - We have again: **a ranking is odd iff it has infinitely many breakpoints.**
 - We enrich the states of \bar{A} with a set of owing states, and choose the accepting states as those in which the set is empty.

Owing states

$$\begin{bmatrix} 2 \\ \perp \end{bmatrix} \xrightarrow{a} \begin{bmatrix} 1 \\ 2 \end{bmatrix} \xrightarrow{b} \begin{bmatrix} 1 \\ \perp \end{bmatrix} \xrightarrow{a} \begin{bmatrix} 1 \\ 0 \end{bmatrix} \xrightarrow{a} \begin{bmatrix} 1 \\ 0 \end{bmatrix} \dots$$

\emptyset

$\{q_1\}$

\emptyset

$\{q_1\}$

\emptyset

Owing states

\emptyset

$\{q_1\}$

$\{q_0\}$

$\{q_0, q_1\}$

$\{q_0\}$

Second draft for \bar{A}

- For our two-state A (the case of more states is analogous):
 - **States**: pairs $\begin{bmatrix} x_1 \\ x_2 \end{bmatrix}, O$ where $\begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$ as in the first draft, and O is a set of owing states (of even rank)
 - **Initial states**: all states of the form $\begin{bmatrix} x_1 \\ \perp \end{bmatrix}, \emptyset$
 - **Transitions**: all $\begin{bmatrix} x_1 \\ x_2 \end{bmatrix}, O \xrightarrow{a} \begin{bmatrix} x'_1 \\ x'_2 \end{bmatrix}, O'$ s.t. ranks don't increase and owing states are correctly updated
 - **Final states**: all states $\begin{bmatrix} x_1 \\ x_2 \end{bmatrix}, \emptyset$

Second draft for \bar{A}

- The runs of \bar{A} on a word w correspond to all the rankings of $dag(w)$.
- The accepting runs of \bar{A} on a word w correspond to all the odd rankings of $dag(w)$.
- Therefore: $L(\bar{A}) = \overline{L(A)}$

Final \bar{A} (the final touch ...)

- We can reduce the number of initial states.
- For every ranking with ranks in the range $[0, 2n]$, changing the rank of all nodes of the first level to $2n$ yields again a ranking. Further, if the old ranking is odd then the new ranking is also odd. So we can simplify the definition of the initial states to:

– Initial state: $\begin{bmatrix} 2n \\ \perp \end{bmatrix}, \emptyset$

An example

- We construct the complements of

$$A_1 = (\{q\}, \{a\}, \delta, \{q\}, \{q\}) \text{ with } \delta(q, a) = \{q\}$$

$$A_2 = (\{q\}, \{a\}, \delta, \{q\}, \emptyset) \text{ with } \delta(q, a) = \{q\}$$

- States of \bar{A}_1 : $\langle 0, \emptyset \rangle, \langle 2, \emptyset \rangle, \langle 0, \{q\} \rangle, \langle 2, \{q\} \rangle$
- States of \bar{A}_2 : $\langle 0, \emptyset \rangle, \langle 1, \emptyset \rangle, \langle 2, \emptyset \rangle, \langle 0, \{q\} \rangle, \langle 2, \{q\} \rangle$
- Initial state of \bar{A}_1 and \bar{A}_2 : $\langle 2, \emptyset \rangle$
- Final states of \bar{A}_1 : $\langle 2, \emptyset \rangle, \langle 0, \emptyset \rangle$ (unreachable)
- Final states of \bar{A}_2 : $\langle 2, \emptyset \rangle, \langle 1, \emptyset \rangle, \langle 0, \emptyset \rangle$ (unreachable)

An example

$\overline{A_1}$

$\overline{A_2}$

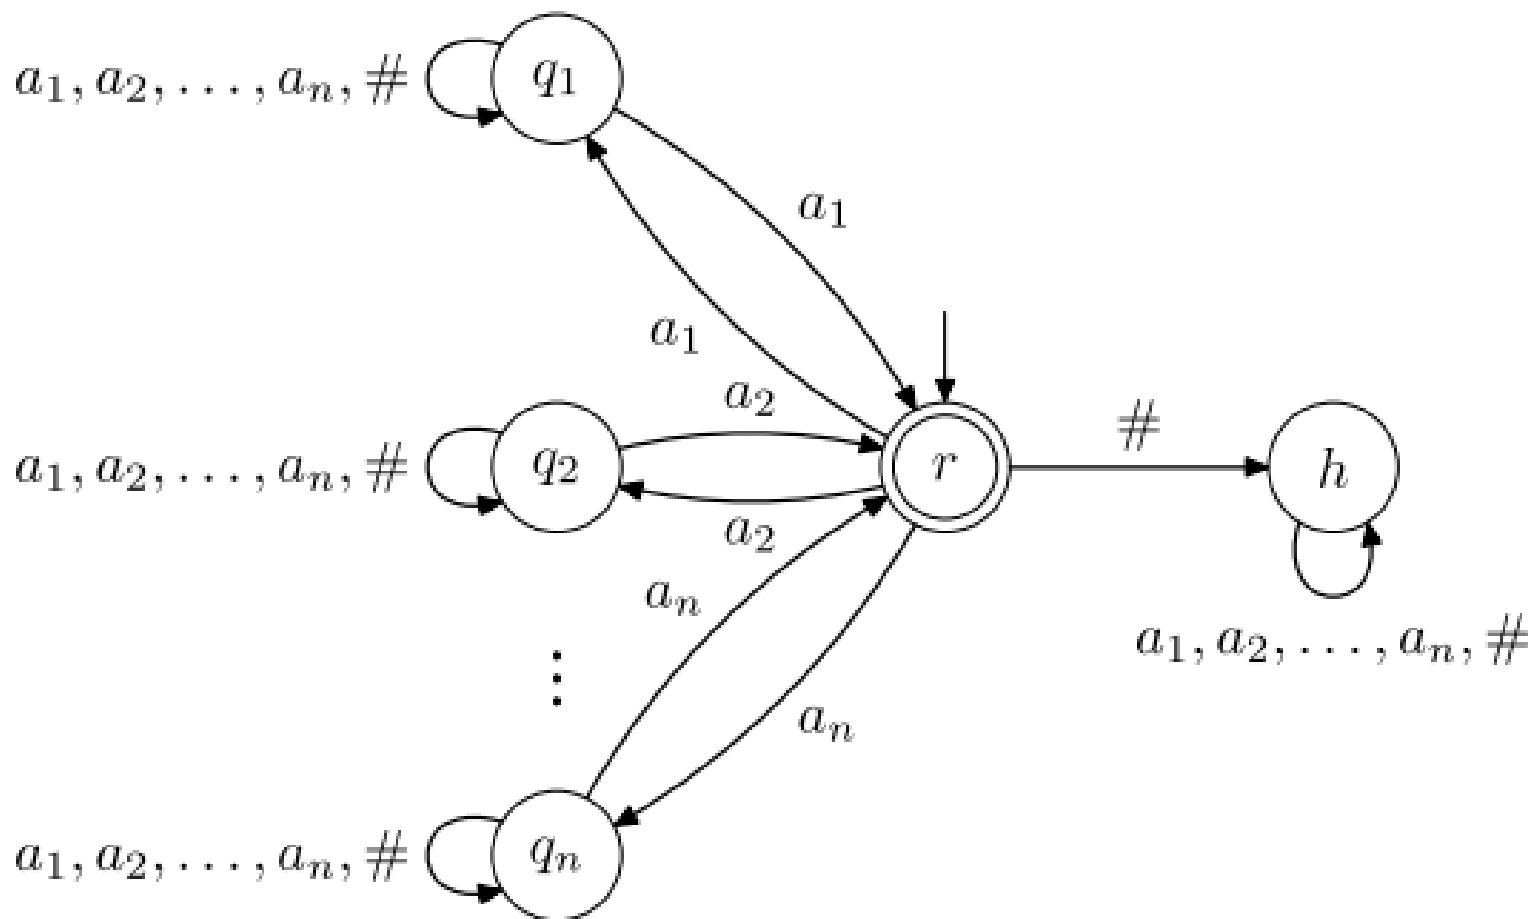

Complexity

- A state consists of a level of a ranking and a set of owing states.
- A level assigns to each state a number of $[0, 2n]$ or the symbol \perp .
- So the complement NBA has at most $(2n + 2)^n \cdot 2^n \in n^{O(n)} = 2^{O(n \log n)}$ states.
- Compare with 2^n for the NFA case.
- We show that the $\log n$ factor is unavoidable.

We define a family $\{L_n\}_{n \geq 1}$ of ω -languages s.t.

- L_n is accepted by a NBA with $n + 2$ states.
- Every NBA accepting $\overline{L_n}$ has at least $n! \in 2^{\Theta(n \log n)}$ states.
- The alphabet of L_n is $\Sigma_n = \{1, 2, \dots, n, \#\}$.
- Assign to a word $w \in \Sigma_n$ a graph $G(w)$ as follows:
 - **Vertices**: the numbers $1, 2, \dots, n$.
 - **Edges**: there is an edge $i \rightarrow j$ iff w contains infinitely many occurrences of ij .
- Define: $w \in L_n$ iff $G(w)$ has a cycle.

- L_n is accepted by a NBA with $n + 2$ states.

Every NBA accepting $\overline{L_n}$ has at least $n! \in 2^{\Theta(n \log n)}$ states.

- Let τ denote a permutation of $1, 2, \dots, n$.
- We have:
 - a) For every τ , the word $(\tau \#)^\omega$ belongs to $\overline{L_n}$ (i.e., its graph contains no cycle).
 - b) For every two distinct τ_1, τ_2 , every word containing inf. many occurrences of τ_1 and inf. many occurrences of τ_2 belongs to L_n .

Every NBA accepting $\overline{L_n}$ has at least $n! \in 2^{\Theta(n \log n)}$ states.

- Assume A recognizes $\overline{L_n}$ and let τ_1, τ_2 distinct. By (a), A has runs ρ_1, ρ_2 accepting $(\tau_1 \#)^\omega$, $(\tau_2 \#)^\omega$. The sets of accepting states visited i.o. by ρ_1, ρ_2 are disjoint.
 - Otherwise we can “interleave” ρ_1, ρ_2 to yield an accepting run for a word with inf. many occurrences of τ_1, τ_2 , contradicting (b).
- So A has at least one accepting state for each permutation, and so at least $n!$ states.
